1. Draw the ER diagram of the database maintained to run a restaurant. Convert the ER diagram into corresponding tables. [10]

now,

Mapping the ER diagram to table

Step I: Mapping strong entity:

• Restaurant

<u>Name</u>	Address	Contact number
-------------	---------	----------------

• Manager

<u>Name</u>	<u>ID. No</u>	Contact no.
-------------	---------------	-------------

• Chef

<u>ID No</u>	Name
--------------	------

• Order

<u>Order No</u>	No. of items
-----------------	--------------

• Bill

<u>Bill no.</u>	Order detail	Price
-----------------	--------------	-------

• Cashier

<u>ID. No</u>	Name
---------------	------

## Step II : Supply & Demand Entity

### • Restaurant

<u>Name</u>	Address	Contact no.
-------------	---------	-------------

### • Manager

<u>Name</u>	<u>ID. No</u>	Contact no.
-------------	---------------	-------------

### • Chef

<u>ID. No</u>	Name
---------------	------

### • Order

<u>Order No.</u>	No. of items
------------------	--------------

### • Bill

<u>Bill no.</u>	Date of bill	Price
-----------------	-----------------	-------

### • Supplier

<u>ID. no</u>	Name
---------------	------

### • Customer

<u>Name</u>	Address	<u>Bill</u> no.	<u>Order</u> no.
-------------	---------	--------------------	---------------------

[ This is a  
Demand entity ]

Step III: Map 1:1 violation steps

• Restaurant

<u>Name</u>	<u>Address</u>	<u>Contact no</u>	<u>Owner ID</u>	<u>Manager ID</u>
-------------	----------------	-------------------	-----------------	-------------------

• Manager

<u>ID No</u>	<u>Name</u>	<u>Contact no.</u>
--------------	-------------	--------------------

• Chef

<u>ID No</u>	<u>Name</u>
--------------	-------------

• Order

<u>Order No</u>	<u>No. of items</u>
-----------------	---------------------

• Bill

<u>Bill no.</u>	<u>Order no.</u>	<u>Price</u>
-----------------	------------------	--------------

• Cashier

<u>ID no</u>	<u>Name</u>
--------------	-------------

• Customer

<u>Name</u>	<u>Address</u>	<u>Bill no</u>	<u>Order no.</u>
-------------	----------------	----------------	------------------

Step 4: Mapping of Attr. 1:N:

• Restaurant

<u>Name</u>	Address	Content no.	Customer ID	Manager ID
-------------	---------	-------------	-------------	------------

• Manager

<u>ID NO</u>	Name	Contact no.
--------------	------	-------------

• Chef

<u>ID NO</u>	Name	Manager ID
--------------	------	------------

• Order

<u>Order No</u>	No. of items	Manager ID
-----------------	--------------	------------

• Bill

<u>Bill no</u>	Order detail	Price	Customer Id
----------------	--------------	-------	-------------

• Cashier

<u>ID no</u>	Name
--------------	------

• Customer

<u>Name</u>	Address	<u>Bill no</u>	<u>Order no</u>	<u>Bill no</u>
-------------	---------	----------------	-----------------	----------------

Step 5:

Mapping M-N relationship

• Restaurant

<u>Name</u>	<u>Address</u>	<u>Contact no.</u>	<u>Chef ID</u>	<u>Manager ID</u>
-------------	----------------	--------------------	----------------	-------------------

• Manager

<u>ID No.</u>	<u>Name</u>	<u>Contact no.</u>
---------------	-------------	--------------------

• Chef

<u>ID no.</u>	<u>Name</u>	<u>Manager ID</u>
---------------	-------------	-------------------

• Order

<u>Order no.</u>	<u>No. of items</u>	<u>Manager ID</u>
------------------	---------------------	-------------------

• Bill

<u>Bill no.</u>	<u>Order detail</u>	<u>Price</u>	<u>Customer ID</u>
-----------------	---------------------	--------------	--------------------

• Cashier

<u>ID no.</u>	<u>Name</u>
---------------	-------------

• Customer

<u>Name</u>	<u>Address</u>	<u>Bill no.</u>	<u>Order no.</u>	<u>Bill no.</u>
-------------	----------------	-----------------	------------------	-----------------

• Place

<u>order no.</u>	<u>Customer name</u>
------------------	----------------------

• prepare

<u>Order no.</u>	<u>Chef ID</u>
------------------	----------------

2. Describe heuristic query optimization along with an example.

[10]

(2)

Many different relational algebra expressions and hence many different query trees can be semantically equivalent, that is they can represent the same query and produce the same results.

The query parser will typically generate a standard initial query tree to correspond to the SQL query without doing any optimization.

A canonical query tree represents a relational algebra expression that is very inefficient if executed directly, because of cartesian product ( $\times$ ) operations.

The heuristic query optimizer will transform this initial query tree into an equivalent final query tree that is efficient to execute.

The optimizer must include rules for equivalence among relational algebra expressions that can be applied to transform the initial tree into the final, optimal query tree.

The way how a query tree is transformed using heuristics is given below:

- 1) Breakup 'select' operations with conjunctive conditions into a cascade of SELECT operations
- 2) Using the commutativity of SELECT with other operations, move each SELECT operation as far down involved in select conditions
- 3) Using commutativity and associativity of binary operations, rearrange the leaf nodes of the tree
- 4) Combine a CARTESIAN PRODUCT operation with a subsequent select operation in the tree into a JOIN operation, if a condition represents a join operation
- 5) Break down and move lots of projection attributes down the tree as far as possible by creating new PROJECT operations as needed
- 6) Identify sub-trees that represent groups of operations that can be executed by a single algorithm

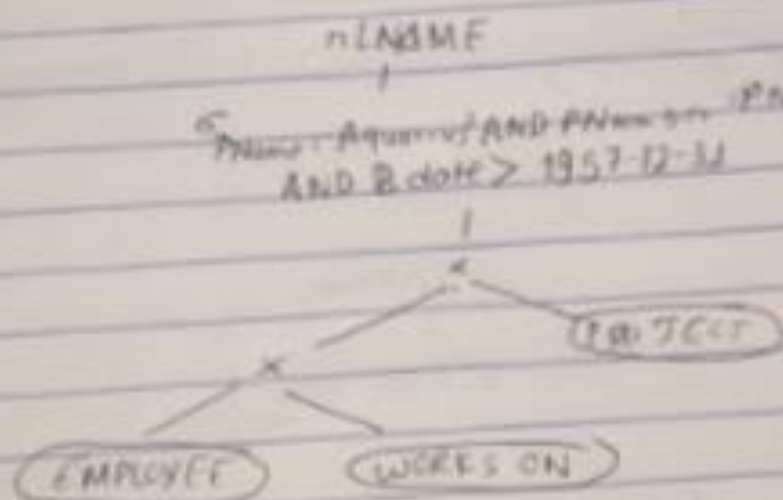

example

Query: Find the last names of employees born of 1957 who work on project named 'Aquarius'.

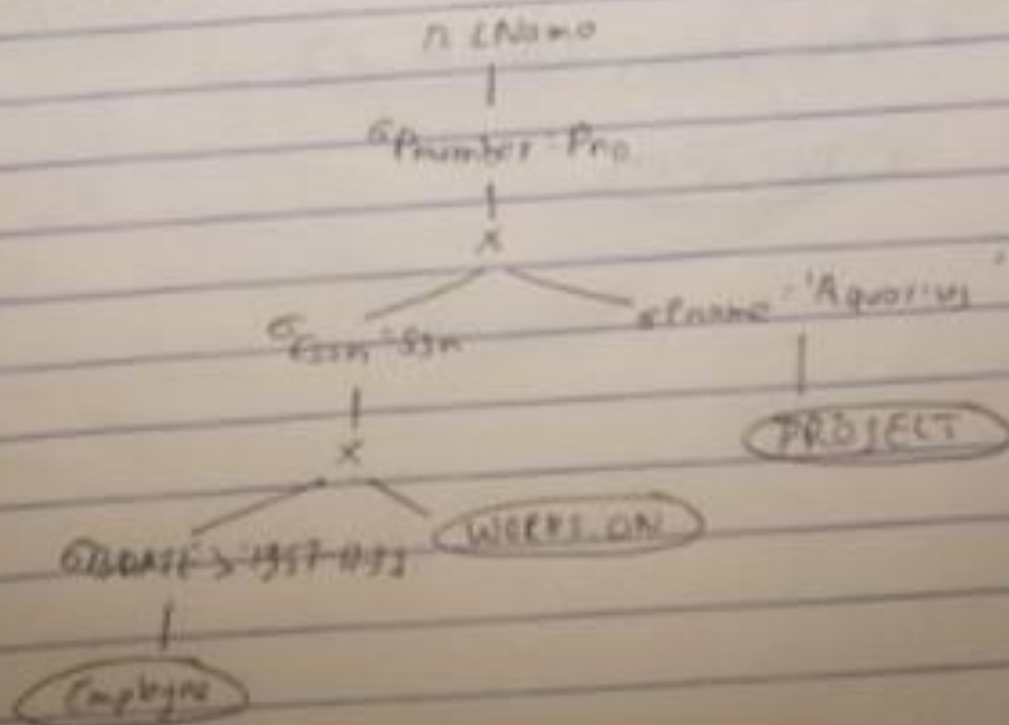

SQL

```
SELECT LNAME  
FROM EMPLOYEE, WORKS_ON PROJECT  
WHERE PNAME = 'Aquarius' AND PNUMBER = 10 AND  
ESSN = SSN AND BDATE > 1957-12-31
```

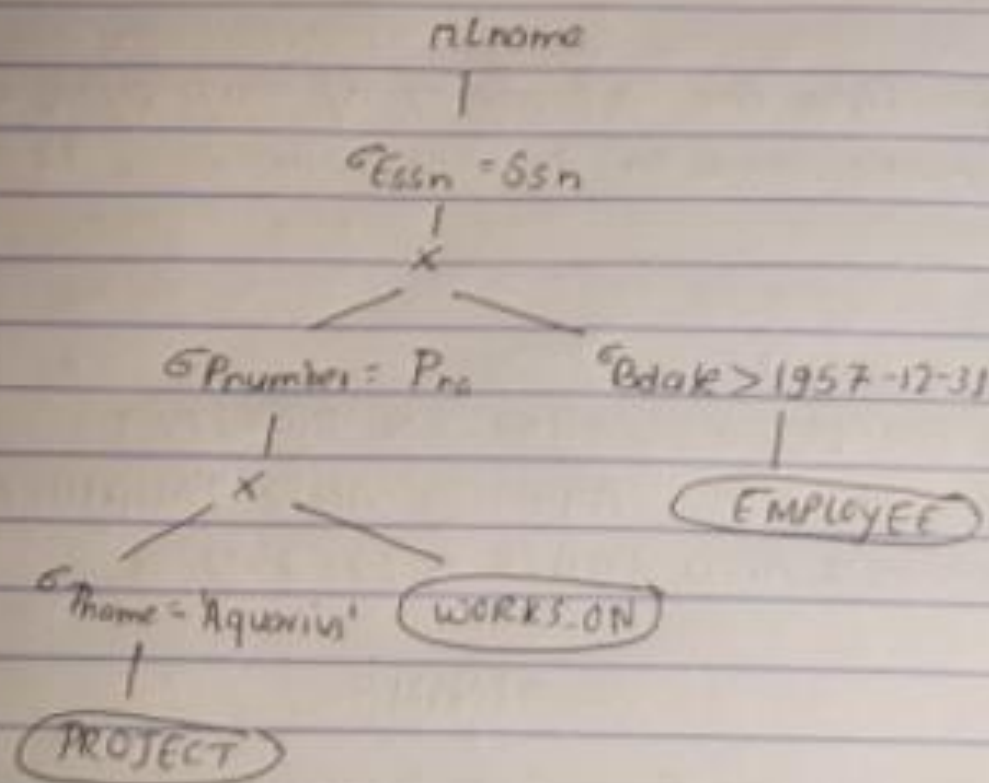

a)

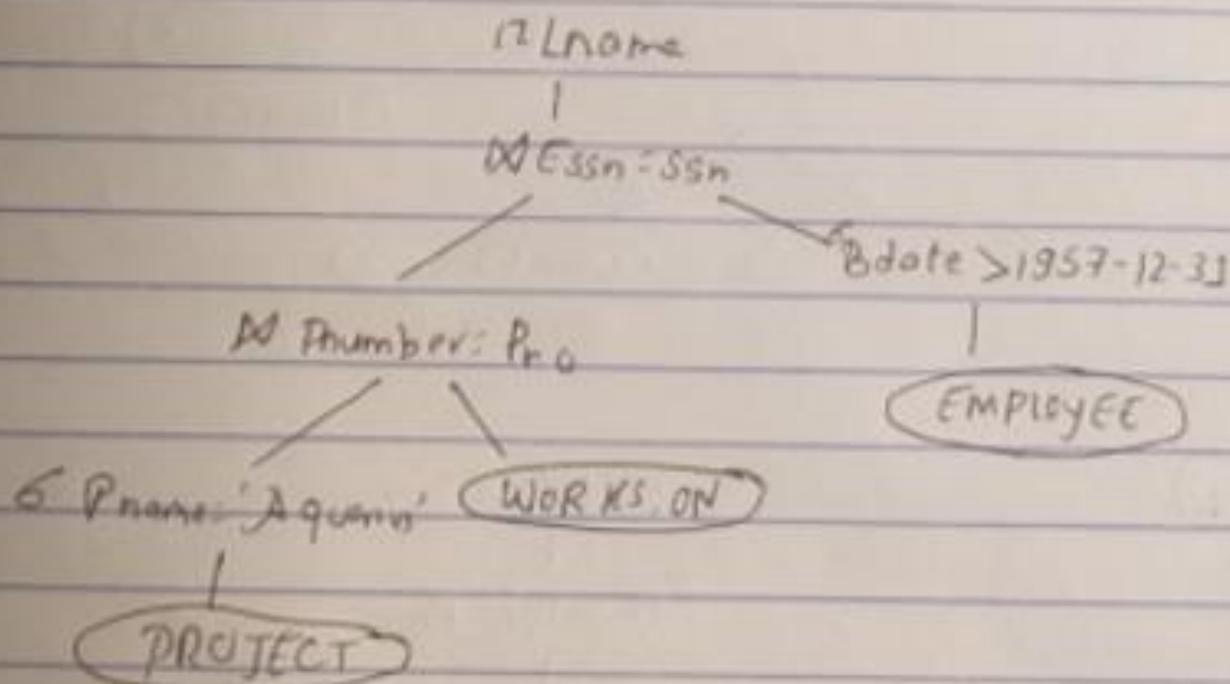

b)

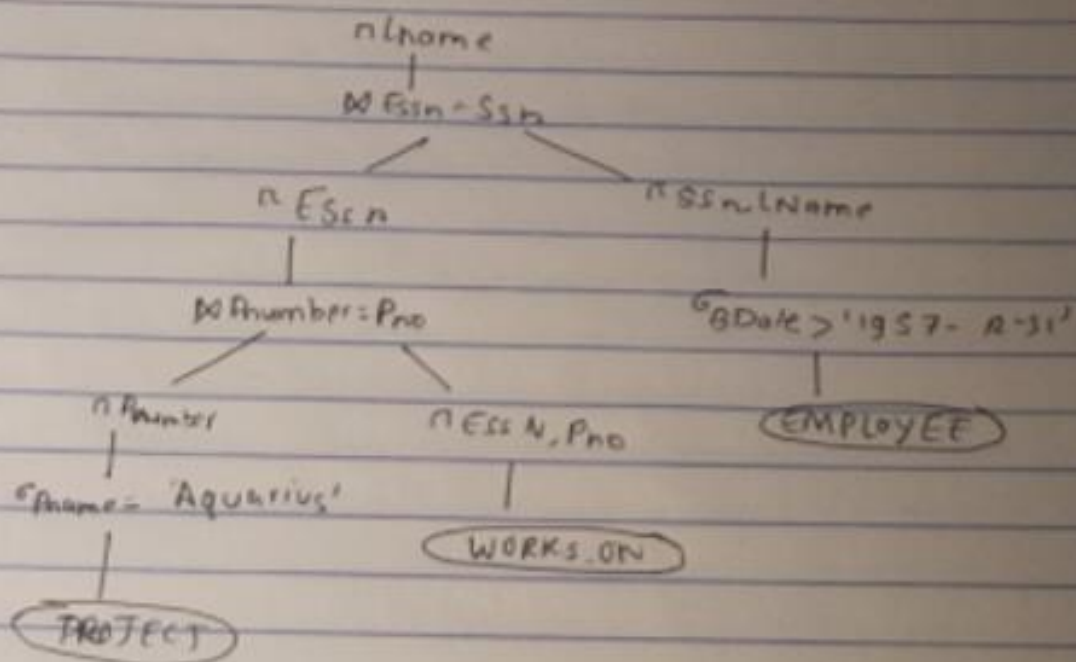

c)

d)

3. Describe the need of 2PL along with an example.

[10]

3

Using binary locks or read/write locks in transaction doesn't guarantee serializability. Schedules on its own. A transaction is said to follow the two-phase locking protocol (2PL) if all locking operations (read-lock, write-lock) precede the first unlock operation in transaction.

The 2PL protocol guarantees serializability. That is one of the need of 2PL protocol.

Let's take up an example to prove this.

Transaction T1 and T2	T <sub>1</sub>	T <sub>2</sub>
As shown in Fig 1 follows two-phase locking protocol because the write-lock(x) operation follows the unlock(V) operation in T <sub>1</sub> and similarly the write-lock(y) operation follows the unlock(x) operation in T <sub>2</sub> .	<pre> read-lock(x); read-item(x); unlock(y); write-lock(x); read-item(x); Y := X + Y; write-item(x); unlock(x); </pre>	<pre> read-lock(x); read-item(x); unlock(x); write-lock(y); read-item(x); Y = X + Y; write-item(y); unlock(x); </pre>

Fig 1

So,

Initial values:  $X = 20, Y = 30$

Result of serial schedule T<sub>1</sub> followed by T<sub>2</sub> we get

$X = 50, Y = 80$

And in the reverse of serial schedule  
 $T_2$  followed by  $T_1$  we get  
 $X = 70, Y = 50$

Here, it doesn't satisfy main test  
 serializability

But if we compare the  
 following example in fig 2;

	$T_1'$	$T_2'$
The given transactions $T_1'$ and $T_2'$ are in serializable order if we maintain order	$read\_lock(Y);$ $read\_item(Y);$ $unlock(Y);$	$read\_lock(X);$ $read\_item(X);$ $unlock(X);$ $write\_lock(X);$ $write\_item(X);$ $Y = X + Y;$ $write\_item(Y);$ $unlock(Y);$
$T_1' \rightarrow T_2'$ or $T_2' \rightarrow T_1'$		
Let $X = 20, Y = 30$		
So,	$write\_lock(X)$	
$X = 20, Y = 50$	$read\_item(X)$	
When $T_1' \rightarrow T_2'$	$X = X + Y;$	
and	$write\_item(X)$	
$X = 20, Y = 50$	$unlock(X)$	
Now		
$T_2' \rightarrow T_1'$		

Moreover, it can be proved that, if every  
execution of the algorithm follows the two-phase  
locking protocol, the schedule is guaranteed to  
be serializable.

2p) Protocol is also a the solution for fast  
update problem and solution for incorrect  
Summary problem respectively.
